

The Grad Cafe dataset is self-reported, meaning applicants voluntarily submit their admission results. This means that there might be selection bias as more applicants are willing to post about their acceptance rather than their rejection skewing the results. Additionally not all the data is added for every type so that also skews the results.

A lot of the analytical results surprised me as they differed from what might have been expected from official results. From the example we can see that the number was higher for the self-reported GRE scores than the actual average and it can be implied that this is also due to the willingness to post your below average scores online compared to higher scores.
